Abstract : In most non-excitabile cells, the depletion of intracellular Ca²⁺ stores activates capacitative Ca²⁺ entry (CCE), which is a Ca²⁺-selective and La³⁺-sensitive entry pathway. Here, we report a novel mechanism of La³⁺-resistant Ca²⁺ entry that is synergistically regulated by B cell receptor (BCR) stimulation and Ca²⁺ store depletion (B-SOC). In the wild-type (WT) DT40 cells, BCR stimulation with anti-IgM antibodies induced Ca²⁺ release and subsequent Ca²⁺ entry in the presence of 0.3 μM La³⁺ which blocks CCE completely. In the inositol 1,4,5-trisphosphate receptor-deficient (IP₃R-KO) cells, BCR stimulation elicited neither Ca²⁺ release nor Ca²⁺ entry. However, under pretreatment of thapsigargin (ThG), BCR stimulation induced La³⁺-resistant Ca²⁺ entry into both WT and IP₃R-KO cells. These results indicate that BCR stimulation and Ca²⁺ store depletion work in concert to activate the La³⁺-resistant Ca²⁺ entry pathway. B-SOC was inhibited by tyrosine kinase inhibitor, genistein. In addition, B-SOC was completely abolished in Stim1-deficient cells and was restored by overexpression of yellow fluorescent protein (YFP)-tagged Stim1, but was unaffected by double knockdown of Orai1/Orai2. These results demonstrate a unique non-CCE pathway, in which Ca²⁺ entry depends on Stim1 and tyrosine kinase activation. It is likely that similar regulation of Ca²⁺ entry occurs in other cell types including salivary gland cells. *J. Med. Invest.* 56 Suppl. : 383-387, December, 2009

INTRODUCTION

Elevation of intracellular Ca²⁺ concentration ([Ca²⁺]_i) is a key signal that regulates a variety of physiological processes (1, 2). This Ca²⁺ signal can

be derived from internal stores or from the extracellular space. Receptor-mediated phospholipase C (PLC) activation generates inositol 1,4,5-trisphosphate (IP₃) and induces Ca²⁺ release from endoplasmic reticulum (ER) stores through the IP₃ receptor (IP₃R). Depletion of intracellular Ca²⁺ stores induces Ca²⁺ entry across the plasma membrane (PM), a phenomenon referred to as capacitative or store-operated Ca²⁺ entry (CCE or SOC, ref. 3, 4). CCE is activated solely via the depletion of Ca²⁺ stores, which can be induced in a PLC-independent manner

by the ER Ca²⁺ pump blocker thapsigargin (ThG) or the Ca²⁺ ionophore ionomycin (3, 4). Thus, IP₃R-mediated Ca²⁺ release from intracellular stores indirectly contributes to CCE activation by physiological stimuli.

Recently, the proteins Stim1 and Orai1 have emerged as candidate components mediating CCE (4-7). Specifically, Stim1 responds to the depletion of Ca²⁺ stores, activating CCE via an interaction with Orai1 (also called CRACM1), a component of the Ca²⁺ release-activated Ca²⁺ (CRAC) channels found in the PM (4, 6, 8, 9). Although it is clear that Stim1 moves close to the PM in response to store depletion and that it activates CCE via Orai1, the mechanisms by which this activation occurs remain unclear.

In the present study, we examined the role of IP₃Rs in BCR-mediated Ca²⁺ entry and demonstrate that these molecules contribute indirectly to La³⁺-resistant Ca²⁺ entry by depleting Ca²⁺ stores. In

addition, our findings reveal that BCR stimulation and Ca²⁺ depletion synergistically activate a novel La³⁺-resistant Ca²⁺ entry pathway in a Stim1-dependent manner. Our results suggest that, in addition to CCE, Stim1 may be involved in the regulation of multiple Ca²⁺ entry pathways.

RESULTS

BCR-mediated La³⁺-resistant Ca²⁺ entry into DT40 cells

In the absence of extracellular Ca²⁺, anti-IgM-mediated BCR activation induced Ca²⁺ responses in most wild-type (WT) DT40 cells. Restoration of extracellular Ca²⁺ and the presence of anti-IgM dramatically increased [Ca²⁺]_i, due to Ca²⁺ entry from the extracellular space. This effect occurred even in the presence of 0.3 μM La³⁺ (Fig. 1A). As shown in Fig. 1B, ThG treatment depleted intracellular Ca²⁺

Figure 1. BCR-mediated La³⁺-resistant Ca²⁺ entry into DT40 cells.

To monitor [Ca²⁺]_i, cells were attached to a small recording chamber coated with 0.5 mg/ml poly-L-lysine and Cellmatrix (diluted 1 : 10). Attached cells were incubated in culture medium for 1 h at 37°C and loaded with 2 μM fura-2/AM. All experiments were performed in PO₄³⁻, SO₄²⁻, CO₂-free HBSS-H at room temperature.

A: WT (black and red) or IP₃R-KO (blue) DT40 cells were stimulated with 3 μg/ml anti-IgM in a nominally Ca²⁺-free medium, followed by the addition of 1.3 mM Ca²⁺ in the absence (black and blue) or presence (red) of 0.3 μM La³⁺. Fluorescence ratios (340 nm/380 nm) were normalized to the ratio obtained just prior to the addition of Ca²⁺ (relative ratios). Upper: pseudocolor images of fura-2 ratios. Lower: normalized fluorescence ratio. Traces are the means ± s.e.m.

B: WT cells were treated with 1 μM ThG in nominally Ca²⁺-free medium, followed by the addition of Ca²⁺ in the absence (black) or presence (red) of La³⁺.

C: WT (black) or IP₃R-KO (blue) cells were pretreated for 10 min with 1 μM ThG in nominally Ca²⁺-free medium and then 2 μg/ml anti-IgM was added in the presence of La³⁺ and Ca²⁺. Modified from ref. 10.

stores and resulted in CCE following the addition of extracellular Ca^{2+} . We did not detect ThG-induced CCE in the presence of $0.3 \mu M La^{3+}$ (Fig. 1B). These results indicate that, unlike ThG treatment alone, BCR-stimulation activates a Ca^{2+} entry pathway that is not inhibited by $0.3 \mu M La^{3+}$ (Fig. 1A, B). Thus, BCR stimulation appears to induce Ca^{2+} entry via a CCE-independent pathway.

La³⁺-resistant Ca²⁺ entry requires depletion of Ca²⁺ stores and BCR stimulation

Next, we examined BCR-mediated La^{3+} -resistant Ca^{2+} entry using DT40 cells treated with ThG. In inositol 1,4,5-trisphosphate receptor-deficient (IP₃R-KO) cells, BCR stimulation elicited neither Ca^{2+} release nor Ca^{2+} entry (Fig. 1A). After depletion of Ca^{2+} with ThG, La^{3+} and Ca^{2+} were added to the cells, followed by BCR stimulation with anti-IgM. BCR-mediated La^{3+} -resistant Ca^{2+} entry was observed in ThG-treated IP₃R-KO DT40 cells as well as in WT cells (Fig. 1C). Our results suggest that the La^{3+} -resistant Ca^{2+} entry pathway is activated by an interaction between BCR stimulation and Ca^{2+} store depletion, and

we propose to name this putative Ca^{2+} entry pathway ‘BCR-mediated store-operated Ca^{2+} entry’ (B-SOC).

B-SOC requires BCR-mediated activation of tyrosine kinase

We examined the mechanisms that occur downstream of BCR stimulation using a tyrosine kinase inhibitor, genistein. In both WT and IP₃R-KO ThG-treated DT40 cells, BCR-mediated La^{3+} -resistant Ca^{2+} entry was diminished by $50 \mu M$ genistein, indicating that B-SOC requires BCR-mediated activation of tyrosine kinase activity (10).

Role of Stim1 in B-SOC

Recent reports have demonstrated that the ER-resident protein Stim1 plays an essential role in SOC (4, 6, 7). We used Stim1-deficient (Stim1-KO) DT40 cells to examine whether Stim1 plays a role in BCR-mediated La^{3+} -resistant Ca^{2+} entry (11). In Stim1-KO DT40 cells, B-SOC was completely abolished (Fig. 2A). In addition, La^{3+} -resistant Ca^{2+} entry was completely restored by overexpression of

Figure 2. Involvement of Stim1 but not Orai1/2 in B-SOC.

A: Involvement of Stim1 in B-SOC

Stim1-KO cells were transfected with the YFP-Stim1 plasmid and Ca^{2+} responses in YFP-positive (black) and YFP-negative (red) cells were examined. Cells were stimulated with $2 \mu g/ml$ anti-IgM in nominally Ca^{2+} -free medium, followed by the addition of La^{3+} and Ca^{2+} . Upper: Fura-2 and YFP fluorescence or pseudocolor images of fura-2 ratios. Lower: normalized fluorescence ratio. Traces are the means \pm s.e.m.

B: Effect of Orai1 and Orai2 siRNAs (siOrai1 and siOrai2) on CCE and B-SOC.

WT cells were co-transfected with the YFP plasmid and siOrai1 and siOrai2.

(a) Cells were treated with ThG in nominally Ca^{2+} -free medium and then Ca^{2+} was added. Black: YFP-transfected cells; Red: YFP-positive siOrai1- and siOrai2-transfected cells.

(b) Cells were treated with ThG in nominally Ca^{2+} -free medium and then $3 \mu g/ml$ anti-IgM was added in the presence of La^{3+} and Ca^{2+} . Black: YFP-transfected cells; Red: YFP-positive siOrai1- and siOrai2-transfected cells. Modified from ref. 10.

yellow fluorescent protein (YFP)-tagged Stim1 (YFP-Stim1; Fig. 2A). Similarly, BCR-mediated Ca²⁺ entry after ThG treatment was not detected in Stim1-KO DT40 cells but restored in YFP-Stim1-expressing DT40 cells (10). These experiments clearly demonstrate that Stim1 plays an essential role in BCR-mediated La³⁺-resistant Ca²⁺ entry.

Orai1 and Orai2 do not play a role in B-SOC

We next examined the effects of Orai1 and Orai2 knockdown on CCE and B-SOC in WT DT40 cells. Co-transfection with Orai1 and Orai2 siRNAs and an YFP plasmid as a transfection marker reduced ThG-induced Ca²⁺ entry (Fig. 2Ba). In contrast, BCR-mediated Ca²⁺ entry after ThG-treatment was not altered by the co-transfection of Orai1 and Orai2 siRNAs (Fig. 2Bb). Together with our finding that B-SOC is not inhibited by the CCE blocker La³⁺, these results provide strong evidence that Stim1 performs an essential role in B-SOC via an Orai-independent pathway.

DISCUSSION

Here, we have described a novel La³⁺-resistant Ca²⁺ entry pathway that is regulated in concert with depletion of Ca²⁺ stores via Stim1- and BCR-mediated activation of tyrosine kinases. We propose calling this novel entry mechanism 'BCR-mediated and store-operated Ca²⁺ entry' (B-SOC). A similar La³⁺-resistant Ca²⁺ entry was observed in Jurkat T cells, where ThG-induced Ca²⁺ entry was completely blocked by 1 μM La³⁺, and subsequent activation of T-cell receptors by anti-CD3 antibodies (3 μg/ml) induced significant Ca²⁺ entry (10).

We found that BCR-mediated Ca²⁺ entry was completely abolished in Stim1-KO DT40 cells and was restored by overexpression of YFP-Stim1. Treatment with the mixture of Orai1 and Orai2 siRNAs did not significantly decrease B-SOC. In addition, total internal reflection fluorescence (TIRF) imaging revealed that partial relocations of YFP-Stim1 were induced by weak BCR stimulation (10). These results suggest that Stim1 has an essential role in the regulation of B-SOC through Orai1-independent pathway. The B-SOC pathway is likely to be the principal route of Ca²⁺ entry, particularly in the presence of weak BCR stimulation. It is likely that similar regulation of Ca²⁺ entry occurs via Stim1-dependent and tyrosine kinase-mediated responses of other cell types including salivary gland cells. Thus, the

physiological roles and mechanisms of B-SOC regulation, including channel properties and molecular interactions, should be explored in future studies.
